

USHA RAO-MONARI Associate Administrator, United Nations Development Programme

much on their size. I think the question is: Never mind the number, [but] how do you get there? And for me, it is a very clever blending of precious public money—public sector money, government money, donor money... whatever—and the private sector that has the scale of finance in its hands. It's a blending of these two things that has to be done, and it's not being done well enough.

Everybody talks about blended finance, but there has to be some models of what that looks like for us to reach this \$92 trillion or whatever number you choose. We cannot reach those numbers without involving the private sector and all other players. You can't expect governments to accomplish it all on their own since they've got conflicting priorities with the money that they have. So, it is going to be a good blend of public and private through the lens of policy, finance and social instruments. And I believe that will form the basis of the blended finance 2.0 model.

At COP26, India said it needs \$1 trillion to meet its climate change goals. So, where can the country source all the funds from?

India, or any country, has to look at both domestic, which has public as well as private sources, and international sources for funds. And people always believe that to get large domestic resources and international capital, they must somehow take action.

What you have to figure out is how to get them up to scale. That is, whether through bonds or other types of financial instruments. I heard that many banks in India are talking about how they are looking at tuning their funding structures. So, whether it's in India or anywhere else, that's where you get the money from.

What should India be focussing on?

Well, if you talk to the African continent, they say, 'We are responsible for only 3 per cent of global emissions. So how much should we focus on decarbonisation? We have only that much to decarbonise.' India's not there. India is somewhere in the middle. In this regard, you better focus on decarbonisation rather than adaptation. In my opinion, it needs both and I think it will do both. By the way, India has a rich history of dealing with these issues. In terms of nature-based solutions and traditional solutions, I think it will bring all of those to the fore.

Technology has been touted as a big driver that can help us but, at the same time, it is the biggest culprit for all the greenhouse gas emissions. So how do you see a balance coming in?

I agree that it is the culprit for all the greenhouse gases. But look, why do people bring technology up as part of the solution? If you think about renewable energy, the new technology around it is what brought the cost of renewable energy down. Now we're looking at battery storage. Then we're looking at green hydrogen and green ammonia. This is all technology, and if we don't use technology as a vehicle towards that greener future, we're never going to get there.

How do you reconcile it with the fact that technology is a culprit? Well, you merely need to be aware that some of these older technologies are, maybe, causing or contributing to emissions. But I don't think that therefore puts a black cross against technology. I don't think we can move forward towards climate sustainability without the use of appropriate technologies. **BT**
