

freshwater sources as they are limited.

Adani Ports and Special Economic Zone (APSEZ) has set up wastewater management systems in prominent ports. So far, APSEZ has recorded treatment and recycling of about 650 million litres of water. Apart from this, the Group's mining businesses practice 100% water recycling.

In Gujarat's Mundra and Karnataka's Udupi, a significant part of the Adani Group's power generating plants' water needs are met by desalinated water. This, in turn, reduces their dependence on freshwater sources. In the Mundra special economic zone (SEZ), a large part of operations utilise saline water. Along with treated water, the Mundra SEZ can meet almost 95% of its needs from these sustainable sources.

Every year, the Adani Group harvests over 2 billion litres of rainwater that can be used to generate about 890 million units of electricity – enough to light up 8.9 million homes for a month.

Prominent solar and wind energy plants of the Adani Group, which has a presence across the country and also abroad, have water harvesting systems.

Apart from this, the Adani Foundation runs water conservation drives in more than 18 states across the country. So far, the initiatives have reached more than 20,000 farmers and farm workers spread across 17,000 acres.

The Adani Group's efforts and initiatives towards sustainability have received several accolades and honours. Earlier this year, Adani Green Energy Limited (AGEL) was certified as Water Positive by DNV, an independent global assurance agency.

Case Study:

Step towards Sustainability: Adani's Godda Power Plant Adopts Zero Water Discharge technique

Power plants are water intensive. At Adani's Godda power plant in Jharkhand, the boilers at two units use up about 3,000 cubic litres of water every hour, which works out to 72,000 cubic litres a day. The water gets converted into steam that powers the turbines, which generate electricity.

The Godda power plant aims to minimise the wastage of water and maximise the utility of unused or excess water. Multiple techniques have been incorporated at the plant in an effort to manage wastewater and ensure minimum or no discharge of industrial wastewater into the environment (this is known as Zero Water Discharge technique). The techniques involve recovery, recycling, and reuse of water.

At the power plant, water is converted into steam to

generate electricity. The excess steam is transferred to a cooling tower where it gets converted back to water. This process ensures that about 80% of the water is utilised again. Some of the wastewater is treated to make it usable for a variety of purposes. A sewage treatment plant is also operational, and water discharged from the plant is used for horticulture and irrigation purposes in local areas. Water stored as part of the rainwater harvesting technique is used for ground water recharge. Such initiatives can help strengthen the water supply and store water for future use. It could be hugely beneficial for areas like Godda as the district in Jharkhand often receives inadequate rainfall and farmers have to depend on local sources to water their fields throughout the year.
